

Distinct models answer different annotation questions

MODEL / EXPERIMENT	MEASURED TARGET	INTERPRETATION BOUNDARY
Shared D · NTv2-500M	TE material (L1), comparator runs (L2) Internal, external and simulated panels	Reference coverage and true model omissions are distinct limitations.
Human hg19 source detector	Apparent FP versus matched background Support under two reference libraries	Additional library agreement is evidence of support, not confirmed biological rescue.
NTv2 representation adaptation	Family-label-free learning on TE-enriched natural copies	Clustering performance is not a measure of genome-wide TE detection.
SF5 class/status model	Complete six-species evaluation Broad TE classes and unresolved statuses	A repaired evaluation denominator does not establish a superfamily annotation tool.
Fixed P3 gaps + NT/seam features	Gap-risk information and admissible whole-gap masking actions	Improved score information need not produce an acceptable masking action.
P3 · GENERanno-derived mask	Tiberius exact-CDS-chain agreement Human, cattle and platypus panels	Pooled gains coexist with local losses; benefit is specific to the mask and workflow.

L1: TE-associated bases. L2: contiguous comparator-run topology. L3: biological insertion identity.
Rows are separate experiments, not stages of one unified model. L3 recovery is not established by these endpoints.
